

What is GRASP?

Greedy Randomized Adaptive Search Procedures (GRASP) is an SLS method that tries to construct a large variety of good initial solutions for a local search algorithm.

- predecessors: semi-greedy heuristics
- tries to combine the advantages of random and greedy solution construction

Thomas Stützle, SA, DLS, GRASP, IG — MN Summerschool, Tenerife, 2003 – p.47

Greedy construction heuristics

- iteratively construct solutions by choosing at each construction step one solution component
 - solution components are rated according to a greedy function
 - the best ranked solutions component is added to the current partial solution
- examples: Kruskal's algorithms for minimum spanning trees, greedy heuristic for the TSP, ...
- **advantage**: generate good quality solutions; local search runs fast and finds typically better solutions than from random initial solutions
- **disadvantage**: do not generate many different solutions; difficulty of iterating

Thomas Stützle, SA, DLS, GRASP, IG — MN Summerschool, Tenerife, 2003 – p.48

Random vs. greedy construction

- random construction
 - high solution quality variance
 - low solution quality
- greedy construction
 - good quality
 - low (no) variance
- goal: exploit advantages of both

Thomas Stützle, SA, DLS, GRASP, IG — MN Summerschool, Tenerife, 2003 – p.49

Semi-greedy heuristics

- add at each step not necessarily the highest rated solution
- repeat until a full solution is constructed:
 - rate solution components according to a greedy function
 - put high rated solution components into a *restricted candidate list* (RCL)
 - choose one element of the RCL randomly and add it to the partial solution
 - adaptive element: greedy function depends on the partial solution constructed so far

Hart, Shogan, 1987

Thomas Stützle, SA, DLS, GRASP, IG — MN Summerschool, Tenerife, 2003 – p.50

Generation of the RCL

- mechanisms for generating RCL
 - **cardinality based**: include the k best rated solution components into RCL
 - **value based**: include all solution components with greedy values better than a given threshold
- min max α based RCL
 - let f_{min} (f_{max}) be greedy values of best (worst) ranked solution component
 - include solution components e with greedy values

$$f(e) \leq f_{min} + \alpha \cdot (f_{max} - f_{min})$$

$\alpha \in [0, 1]$ is a parameter

- $\alpha = 0$ corresponds to a greedy construction heuristic
- $\alpha = 1$ corresponds to a random solution construction

Thomas Stützle, SA, DLS, GRASP, IG — MN Summerschool, Tenerife, 2003 – p.51

GRASP

- GRASP tries to capture advantages of random and greedy solution construction
- iterate through
 - randomized solution construction exploiting a greedy probabilistic bias to construct feasible solutions
 - apply local search to improve over the constructed solution
- keep track of the best solution found so far and return it at the end

GRASP — local search

- local search from random solutions
 - high variance
 - best solution quality often better than greedy (if not too large instances)
 - average solution quality worse than greedy
 - local search requires many improvement steps
- local search from greedy solutions
 - average solution quality better than random
 - local search typically requires only a few improvement steps
 - low (no) variance

Thomas Stützle, SA, DLS, GRASP, IG — MN Summerschool, Tenerife, 2003 – p.53

GRASP — Procedural view

procedure *GRASP*

 Initialize Parameter

while (termination condition not met) **do**

$s = \text{ConstructGreedyRandomizedSolution}()$

$s' = \text{LocalSearch}(s)$

if $f(s') < f(s_{best})$

$s_{best} = s'$

end

return s_{best}

end *GRASP*

Thomas Stützle, SA, DLS, GRASP, IG — MN Summerschool, Tenerife, 2003 – p.54

GRASP Example: SAT

- solution components are value assignment to variables
- greedy-Function
 - number of still unsatisfied clauses that would become satisfied by a value assignment
 - Φ_i^+ : set of additionally satisfied clauses if $x_i = \text{true}$
 - Φ_i^- : set of additionally satisfied clauses if $x_i = \text{false}$
- min max α based RCL
 - Let $\Phi^* = \max\{|\Phi_i^+|, |\Phi_i^-|\}$ over all free variables x_i
 - $x_i = \text{true} \in \text{RCL}$ if $|\Phi_i^+| \geq \alpha \cdot \Phi^*$
 - $x_i = \text{false} \in \text{RCL}$ if $|\Phi_i^-| \geq \alpha \cdot \Phi^*$

Thomas Stützle, SA, DLS, GRASP, IG — MN Summerschool, Tenerife, 2003 – p.55

GRASP Example: SAT

- variable selection
 - if an unsatisfied clause contains only one single still uninstantiated variable, try to satisfy this clause
 - otherwise choose randomly an element from the RCL
- local search
 - best-improvement 1-opt local search (GSAT architecture)
- performance
 - at the time the research was done reasonably good performance
 - however, nowadays by far outperformed by more recent local search algorithms for SAT
 - the same is true for weighted MAX-SAT

Thomas Stützle, SA, DLS, GRASP, IG — MN Summerschool, Tenerife, 2003 – p.56

GRASP extensions

- convergence of GRASP (not guaranteed if $\alpha \neq 1$)
- introduction of a bias when choosing elements from the RCL
 - different possibilities of using, e.g. ranks (e.g. $\text{bias}(r) = 1/r$)
 - choose a solution component with a probability proportional to bias
- reactive GRASP (tuning of α)
- addition of a type of long term memory to bias search
 - path relinking
 - use of previous elite solutions to guide construction
- parallelization of GRASP

Thomas Stützle, SA, DLS, GRASP, IG — MN Summerschool, Tenerife, 2003 – p.57

GRASP — concluding remarks

- straightforward extension of construction heuristics
- easy to implement
- few parameters
- many different applications available
- several extensions exist
- can be used to generate initial population in population-based methods
- however, as a stand-alone procedure often not state-of-the-art results

Thomas Stützle, SA, DLS, GRASP, IG — MN Summerschool, Tenerife, 2003 – p.58
